

Feedback From Saqlain (4 Aug 2026)

Completed items, verified on the live site (inventory.scaletopia.io)

Auto-Mapping (GHL + EmailBison)

- Clean company names are pushed, not raw or unclean versions.
- Auto-mapping is not silent. After it maps the fields automatically, a preview screen (same style as the Import feature) lists all fields and where they are mapped, and any mapping can be changed manually before confirming the push.

GHL Push

- The custom field mapping screen always appears when pushing to GHL, not only when a custom data filter is active. If a custom field has no data to map, it is left empty but still shown in the mapping UI.
- The tag format supports custom additions. Extra identifiers (for example leadership, marketing, or a segment name) can be appended to the tag while the base format stays intact, and helper text shows the format so the user knows the structure and where the addition goes.

EmailBison Push

- Custom enrichment and custom data fields are available in the column mapping dropdown. All enrichment columns from custom_data are options, not just the standard fields.
- Custom variables are auto-created in the EmailBison workspace when they do not already exist.
- The custom fields shown in the mapping UI are accurate and fetched live from the EmailBison API, so the list is always current.
- After a new custom variable is created, the list updates without a manual page refresh.
- A Create Campaign option is available in the push flow for cases where the campaign does not already exist in the workspace.

Custom Data Filtration

- The filter no longer queries on every keystroke. It is debounced and runs once typing settles instead of on each character.
- The "contains" filter accepts multiple values as chips. Pressing Enter after a value creates a chip, and multiple values can be added one by one (same as Clay's filter UX), instead of a comma-separated text field.

Push Activity (Background Jobs)

- Pushes run as background jobs instead of blocking on the push screen until the whole import completes.
- A Push Activity panel shows active and completed pushes with client name, platform (GHL or EmailBison), niche, who triggered the push, and timestamp.

- A live progress bar shows how many contacts have been processed out of the total.
- The completion summary shows total selected, created, updated, and failed.
- Queueing is supported. If a push is already running and another is triggered, it is queued and starts automatically when the current one completes.
- Each completed push has two action buttons. View Contacts opens the People table filtered to the contacts from that push, and View Companies does the same for the Companies table.

Push Status Filters in People and Companies Tables

- Both tables have a push status filter that is client specific. "Not yet pushed to GHL for [client]" shows only contacts not yet imported for that client, and "Already pushed to GHL for [client]" shows contacts already imported for that client.
- The logic is client-aware. If some contacts were pushed to one client, filtering for that client shows only the remaining ones, while another client shows the full set.
- The same filter applies for EmailBison pushes as well.
