

Performance Improvements

Summary · 22–26 July 2026 · Shipped to **main**

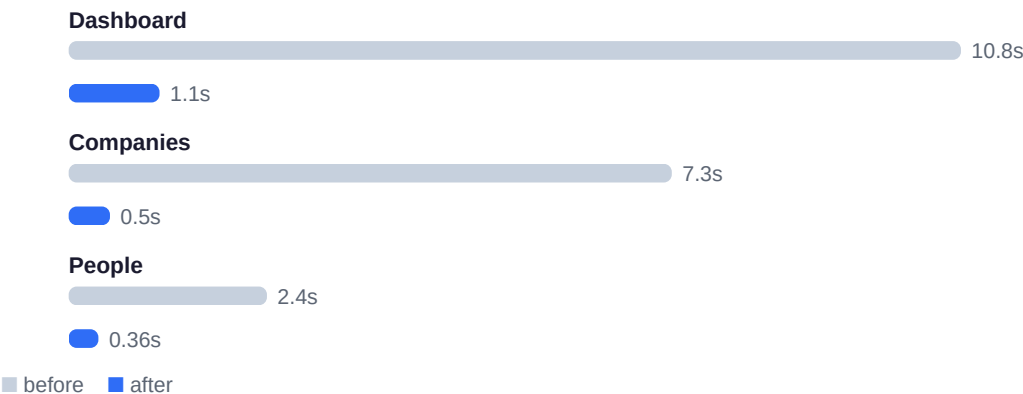

Over the last few days we cut page load times across the app from **several seconds to under one second** on the heaviest pages. The work moved slow, in-app data crunching into the database, removed redundant authentication round-trips, and stopped pages from waiting on queries one after another.

How much faster

Page	Before	After	Faster by
Dashboard	~10.8 s	~1.1 s	≈ 10×
Companies	~7.3 s	~0.5 s	≈ 14×
People	~2.4 s	~0.36 s	≈ 6.5×
Company detail	~0.66 s	~0.34 s	≈ 2×
Person detail	~0.67 s	~0.33 s	≈ 2×

Every authenticated page and API route also benefits from a faster login / session check applied app-wide.

At a glance

What we changed

- 1 Dashboard totals computed in the database.**
Replaced scanning 100k+ rows into the app and adding them up in JavaScript with a single database summary call.
- 2 Companies & People lists filter and paginate in the database.**
Only the 50 rows on screen are fetched, instead of pulling the entire table on every visit.
- 3 Faster session checks everywhere.**
Login and permission checks verify the session locally and read the user's role straight from the sign-in token, removing a network round-trip on every page and API call.

4

Detail pages stopped waiting in line.

Company and person pages load their data in parallel (or in one combined query) instead of one query after another.

Bottom line: the three heaviest pages — Dashboard, Companies, People — all went from multiple seconds to well under a second. Detail pages are roughly twice as fast, and the whole app feels quicker to log in and navigate.

*Measured against the live database using the repeatable benchmarks in `scripts/bench-dashboard.ts` and `scripts/bench-pages.ts`.
Figures are query / data-fetch times, the part these changes touched.*
